# Best Practices in DNS Anycast Service-Provision Architecture

Version 1.1

March 2006

Bill Woodcock

Gaurab Raj Upadhaya

# It's all Anycast

Large ISPs have been running production anycast DNS for more than a decade.

Which is a very long time, in Internet years.

95% of the root nameservers are anycast.

The large gTLDs are anycast.

# Reasons for Anycast

Transparent fail-over redundancy

Latency reduction

Load balancing

Attack mitigation

Configuration simplicity (for end users) or lack of IP addresses (for the root)

## No Free Lunch

The two largest benefits, fail-over redundancy and latency reduction, both require a bit of work to operate as you’d wish.

# Fail-Over Redundancy

DNS resolvers have their own fail-over mechanism, which works... um... okay.

Anycast is a very large hammer.

Good deployments allow these two mechanisms to reinforce each other, rather than allowing anycast to foil the resolvers' fail-over mechanism.

# Resolvers’ Fail-Over Mechanism

DNS resolvers like those in your computers, and in referring authoritative servers, can and often do maintain a ***list*** of nameservers to which they’ll send queries.

Resolver implementations differ in how they use that list, but basically, when a server doesn’t reply in a timely fashion, resolvers will try another server from the list.

# Anycast Fail-Over Mechanism

Anycast is simply layer-3 routing.

A resolver's query will be routed to the topologically nearest instance of the anycast server visible in the routing table.

Anycast servers govern their own visibility.

Latency depends upon the delays imposed by that topologically short path.

# Conflict Between These Mechanisms

Resolvers measure by latency.

Anycast measures by hop-count.

They don’t necessarily yield the same answer.

Anycast always trumps resolvers, if it’s allowed to.

Neither the DNS service provider nor the user are likely to care about hop-count.

Both care a great deal about latency.

# How The Conflict Plays Out

Packet Clearing House

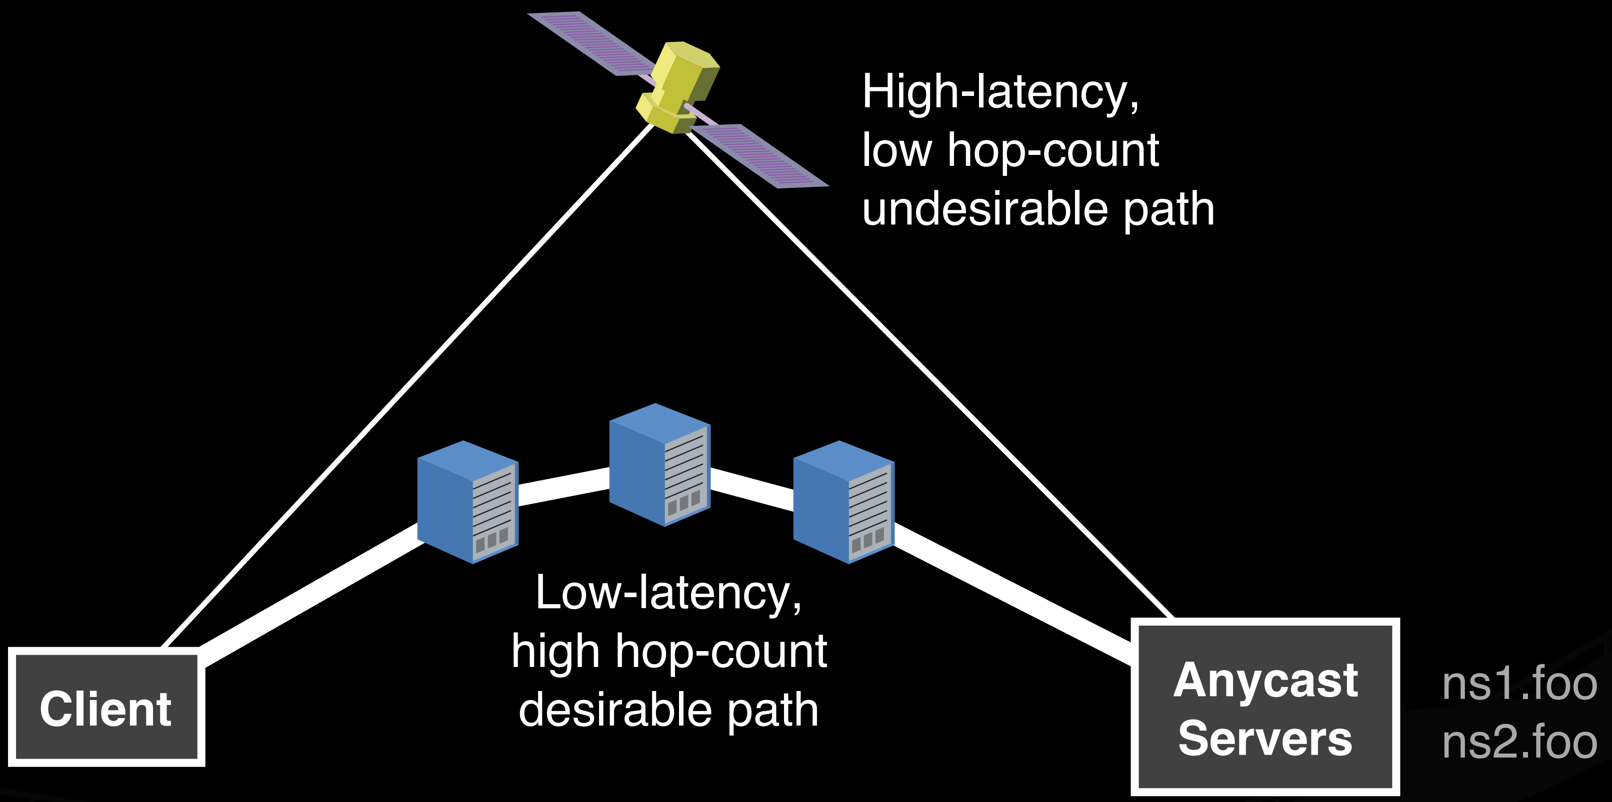
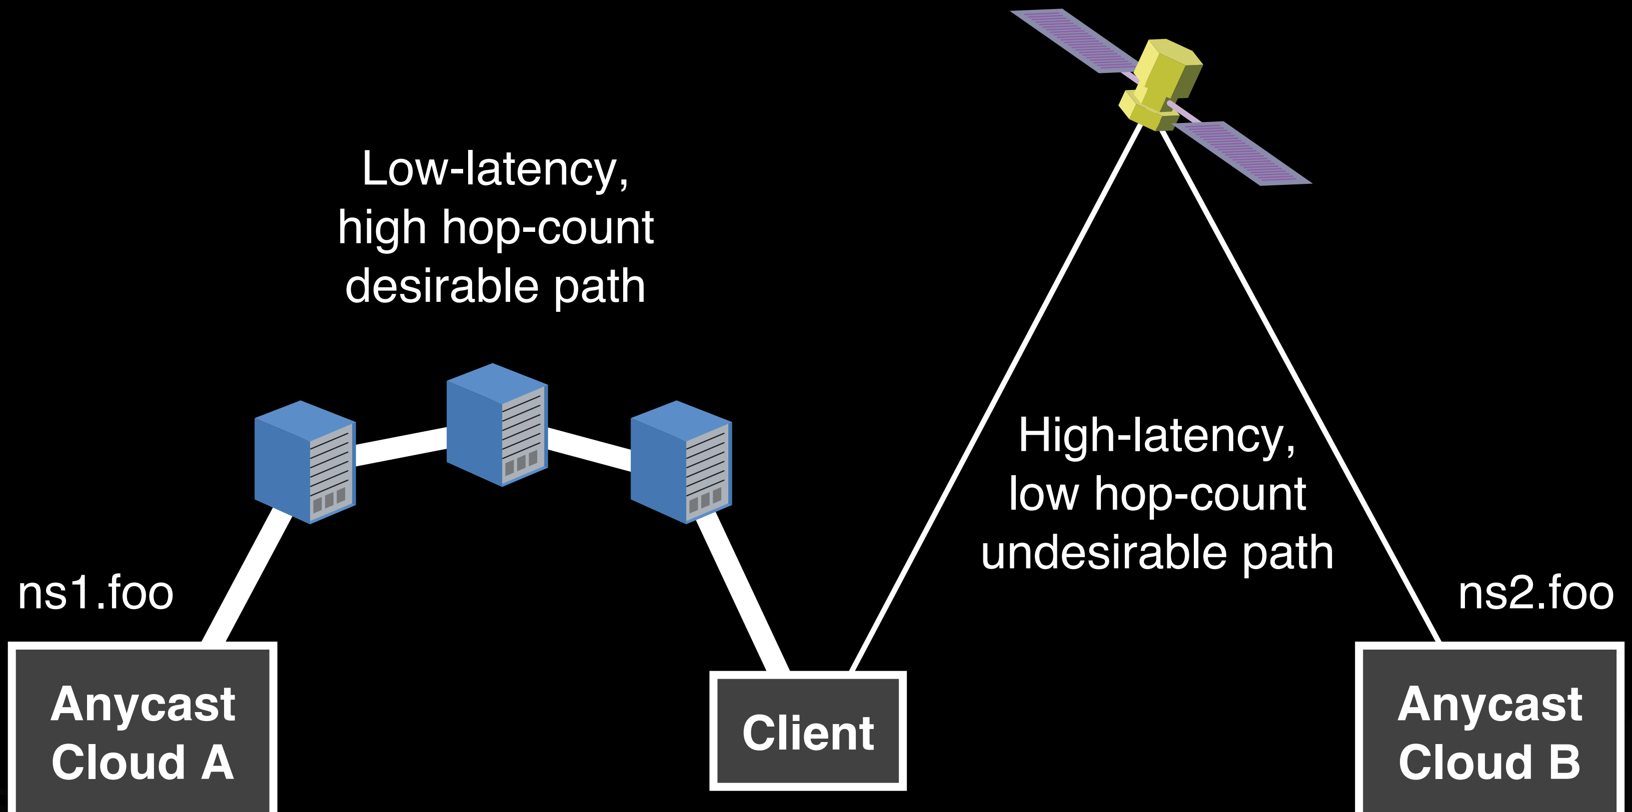
# Resolve the Conflict



The resolver uses different IP addresses for its fail-over mechanism, while anycast uses the same IP addresses.

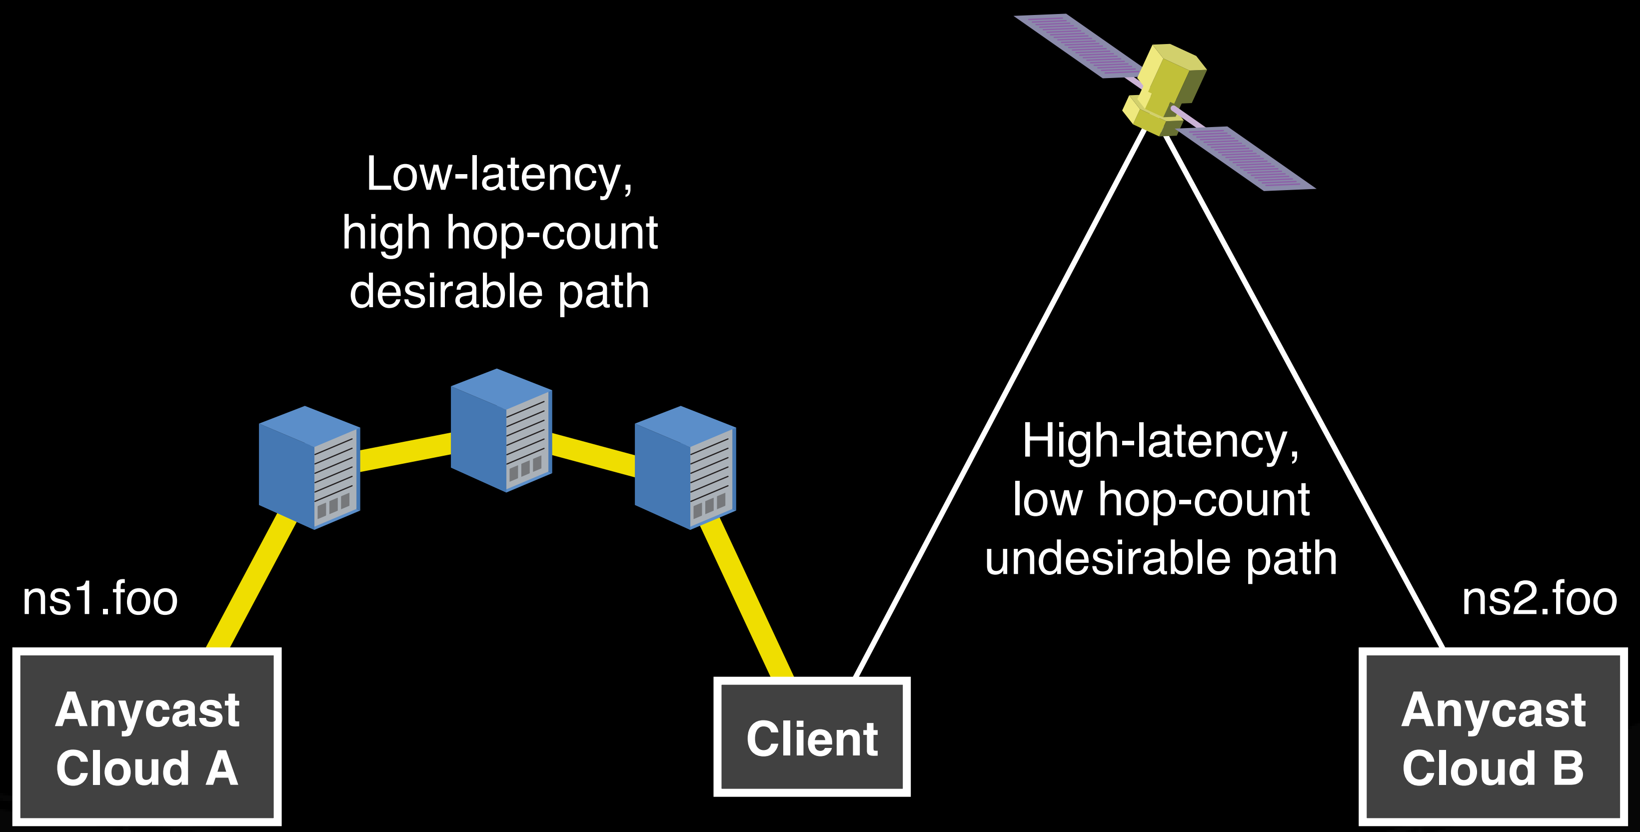
# Resolve the Conflict



Split the anycast deployment into “clouds” of locations, each cloud using a different IP address and different routing policies.

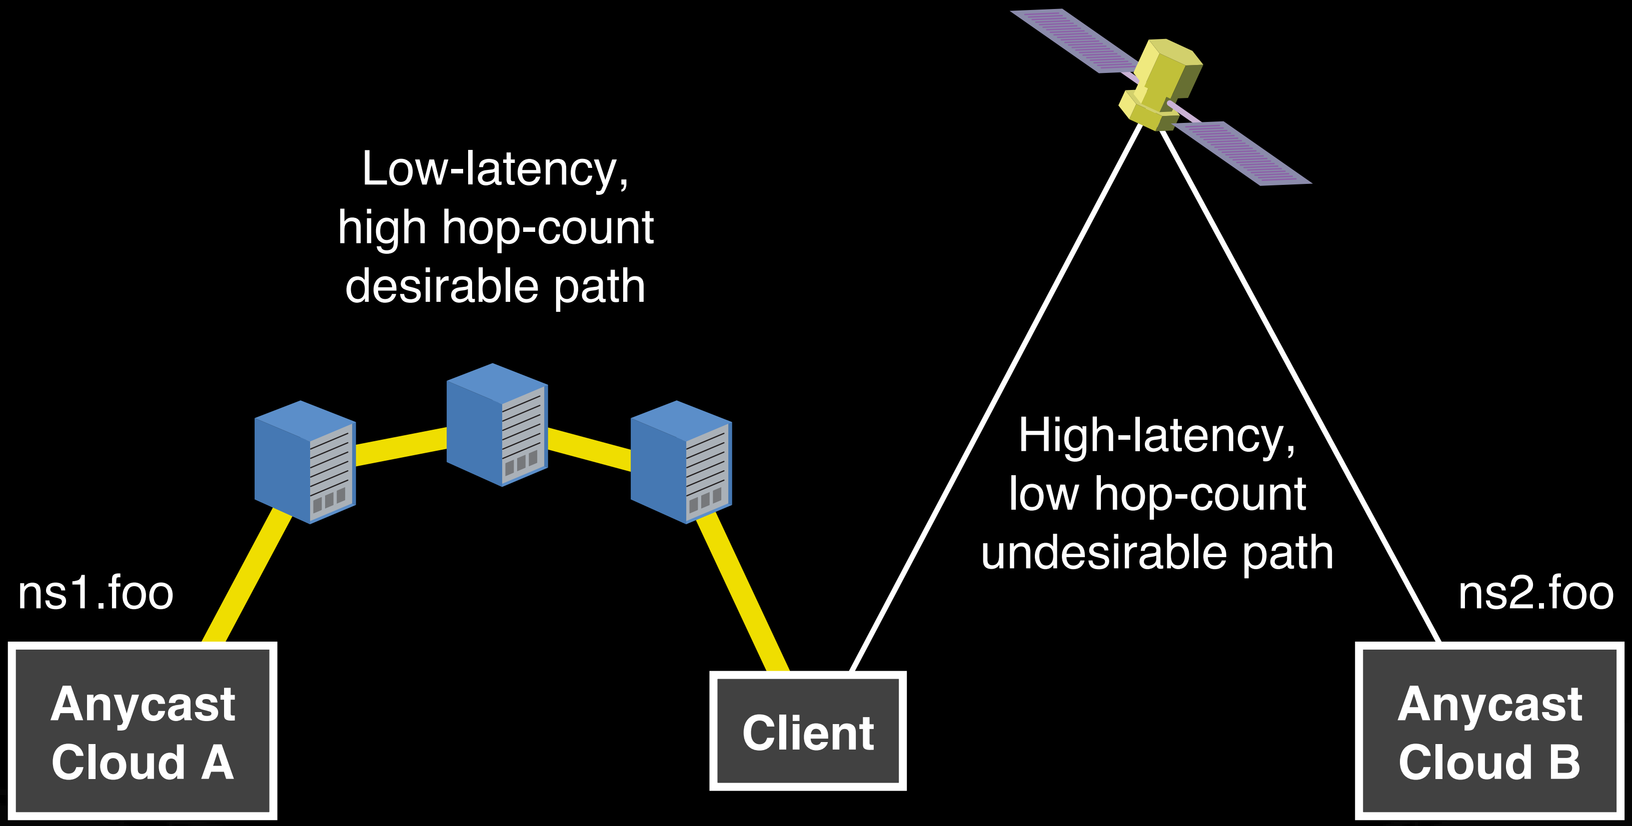
PCH
Packet Clearing House

# Resolve the Conflict



This allows anycast to present the nearest servers,
and allows the resolver to choose the one which performs best.

# Resolve the Conflict



These clouds are usually referred to as “A Cloud” and “B Cloud.”
The number of clouds depends on stability and scale trade-offs.

# Latency Reduction

Latency reduction depends upon the native layer-3 routing of the Internet.

The theory is that the Internet will deliver packets using the shortest path.

The reality is that the Internet will deliver packets according to ISPs' policies.

# Latency Reduction

ISPs' routing policies differ from shortest-path where there's an economic incentive to deliver by a longer path.

# ISPs' Economic Incentives (Grossly Simplified)

ISPs have  high cost to deliver traffic through transit.

ISPs have a low cost to deliver traffic through their peering.

ISPs receive money when they deliver traffic to their customers.

Packet Clearing House

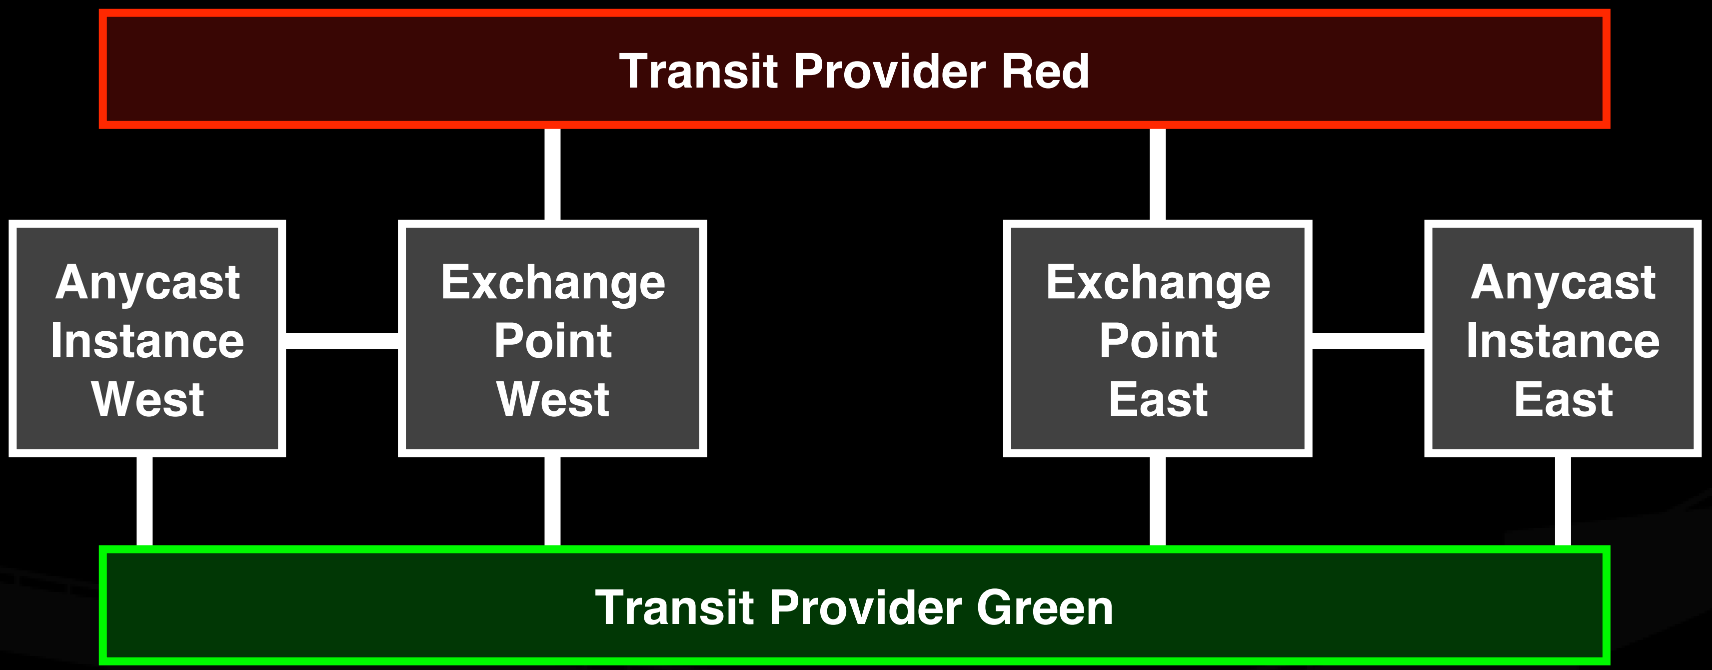
# ISPs' Economic Incentives (Grossly Simplified)

Therefore, ISPs will deliver traffic to a customer across a longer path, before by peering or transit across a shorter path.

If you are both a customer, and a customer of a peer or transit provider, this has important implications.

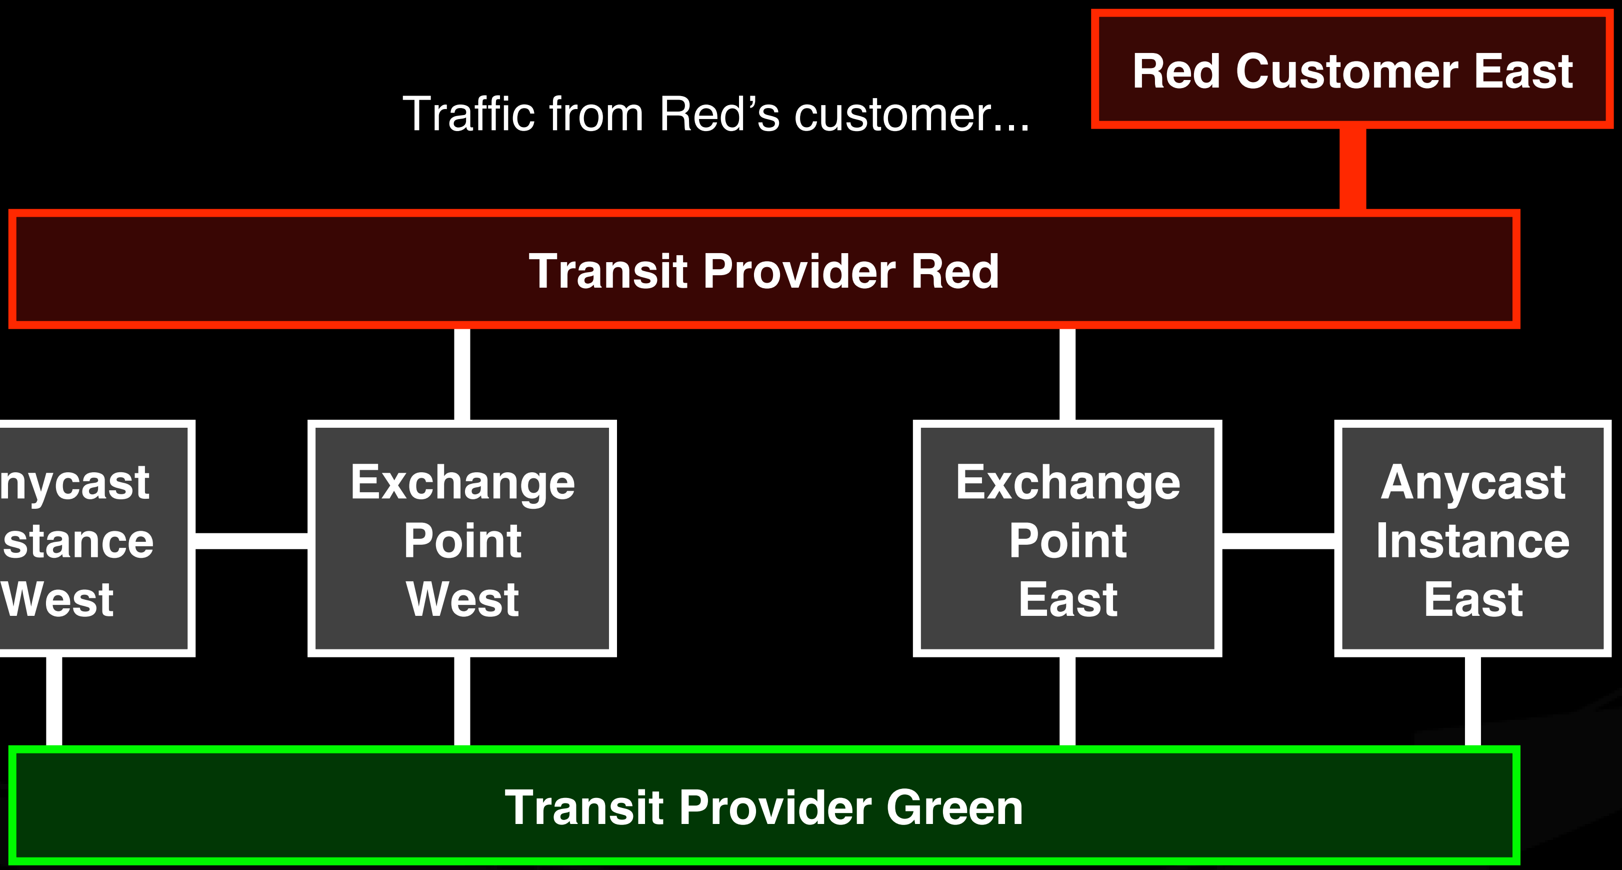
# Normal Hot-Potato Routing

If the anycast network is not a customer of large Transit Provider Red...



...but is a customer of large Transit Provider Green...

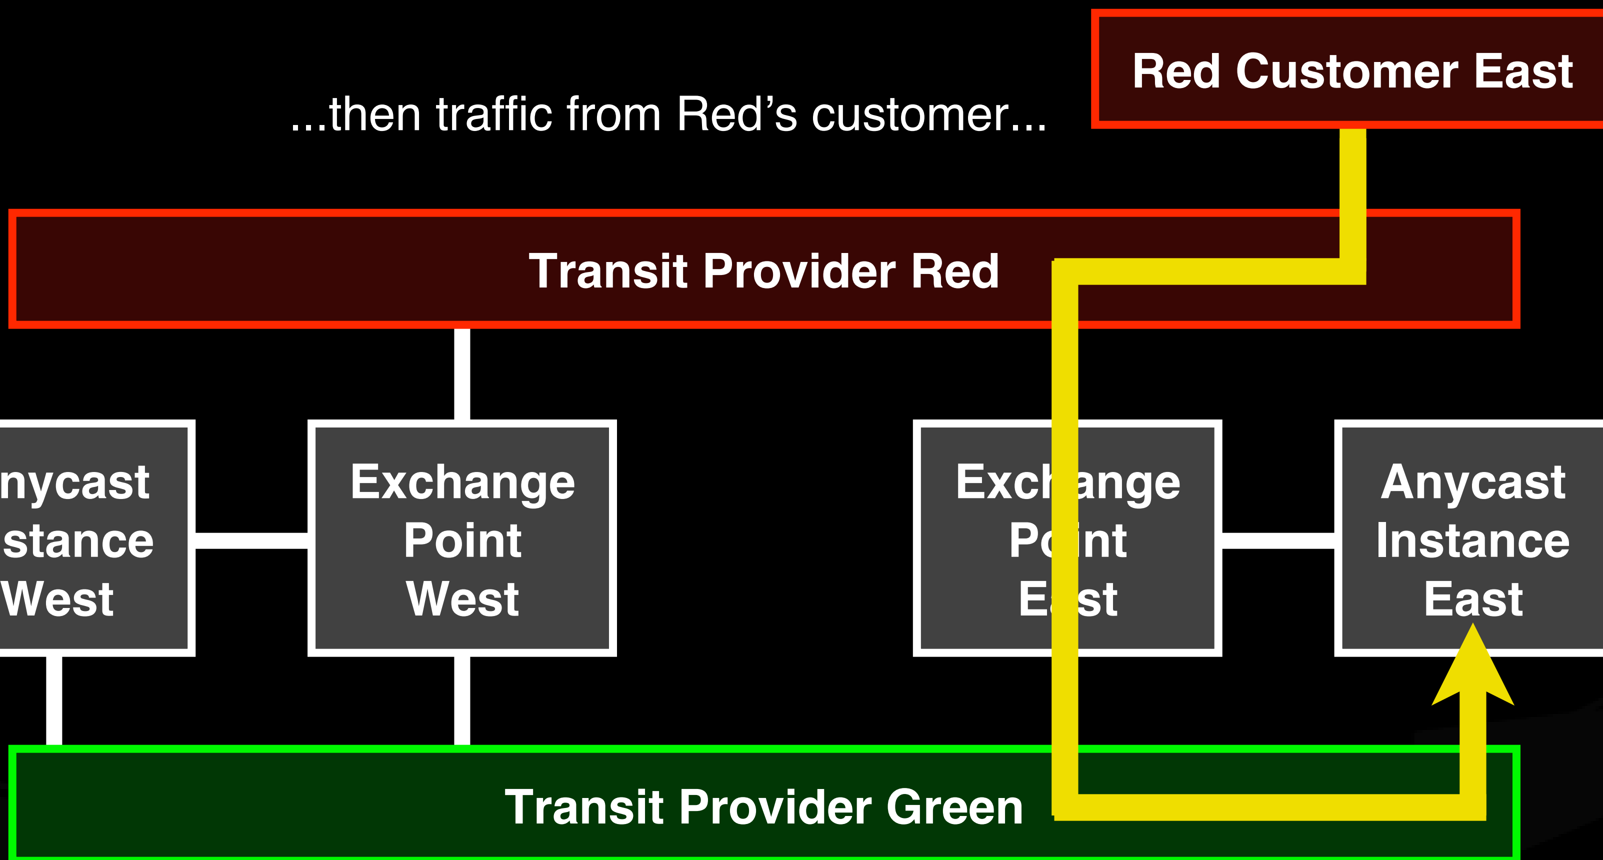
# Normal Hot-Potato Routing



PCH Packet Clearing House

# Normal Hot-Potato Routing

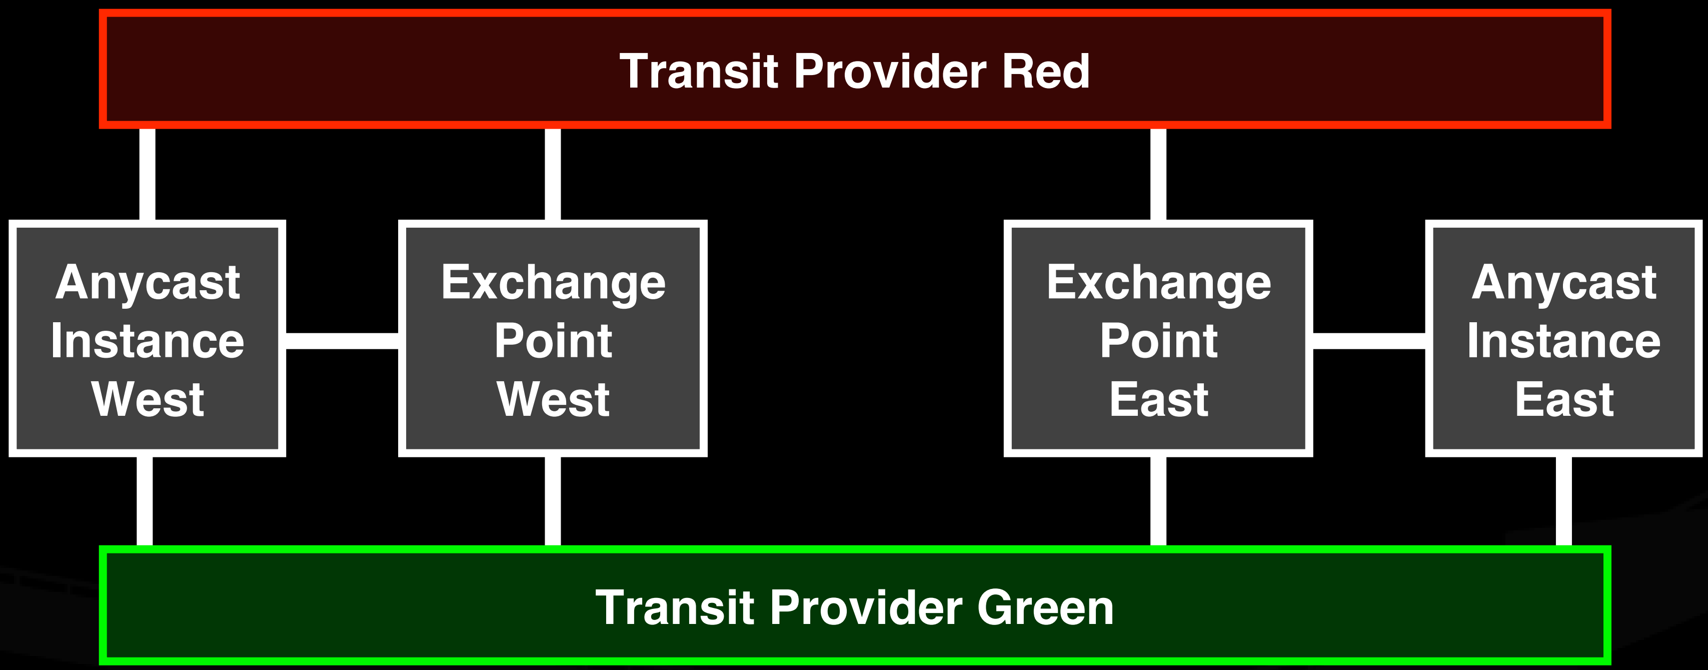
...then traffic from Red's customer...



...is delivered from Red to Green via local peering, and reaches the local anycast instance.

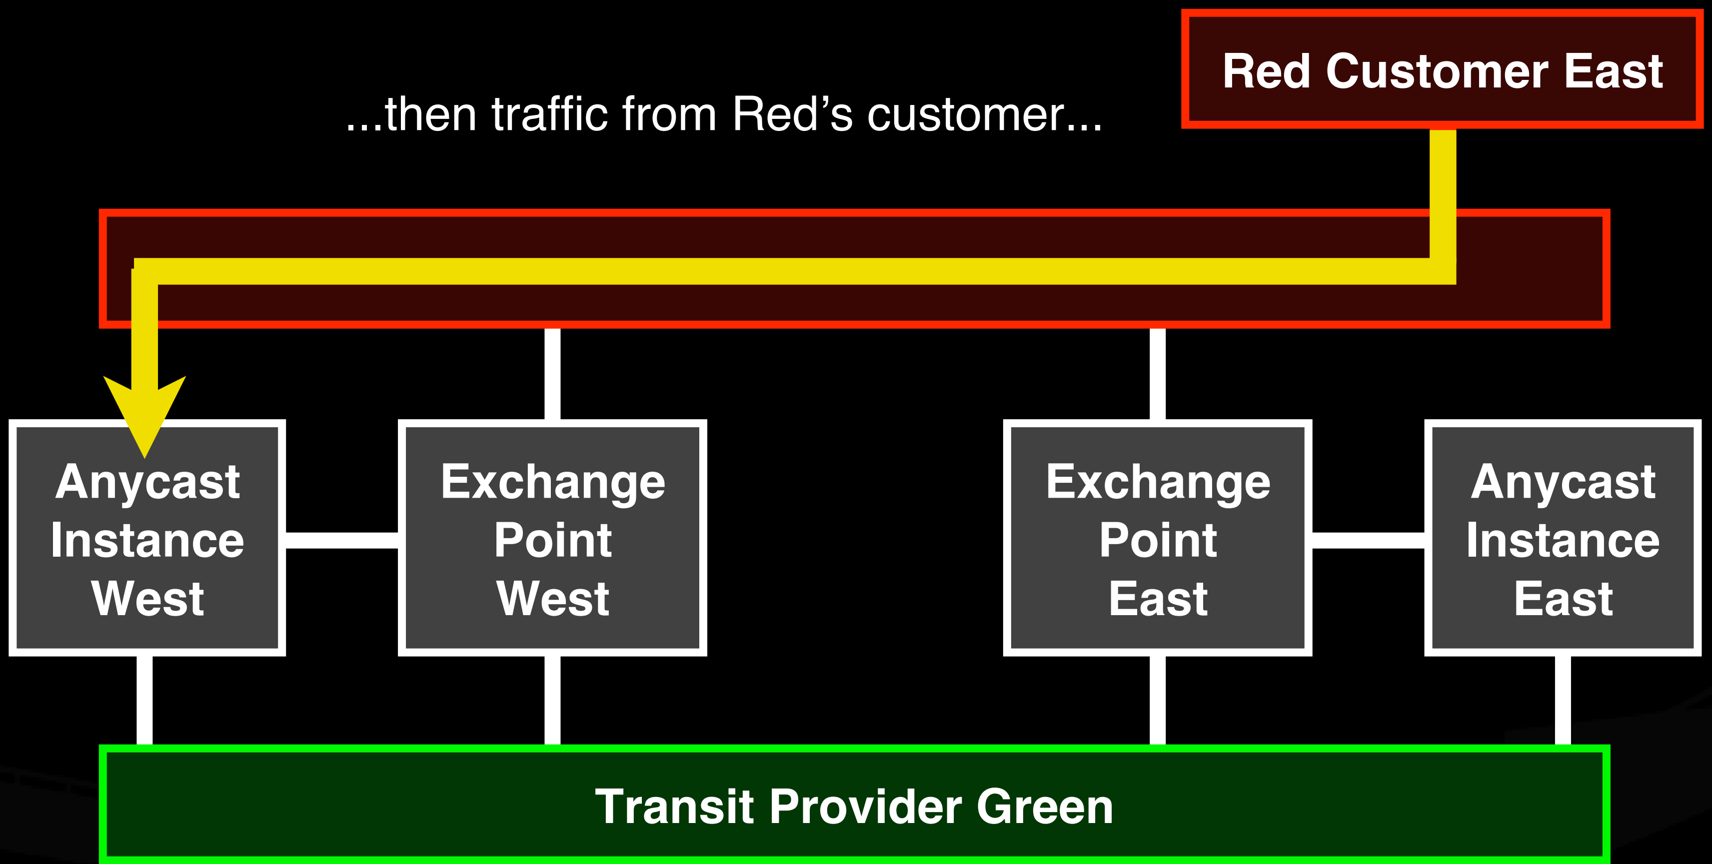
# How the Conflict Plays Out

But if the anycast network is a customer of both large Transit Provider Red...



...and of large Transit Provider Green, but not at all locations...

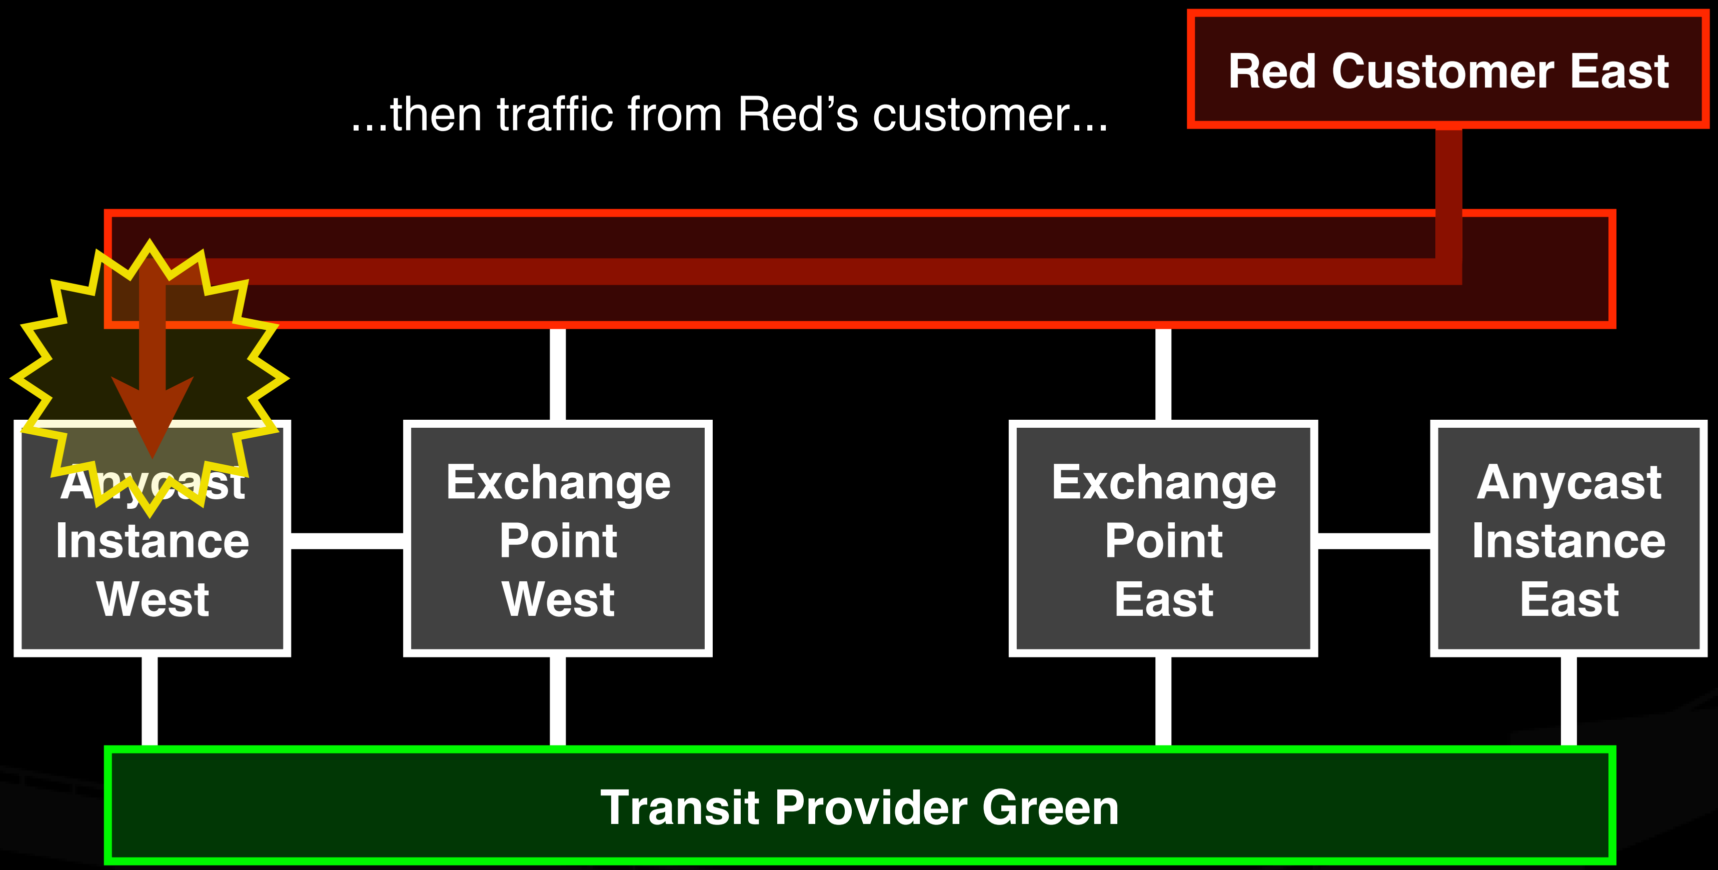
# How the Conflict Plays Out



...will be misdelivered to the remote anycast instance...

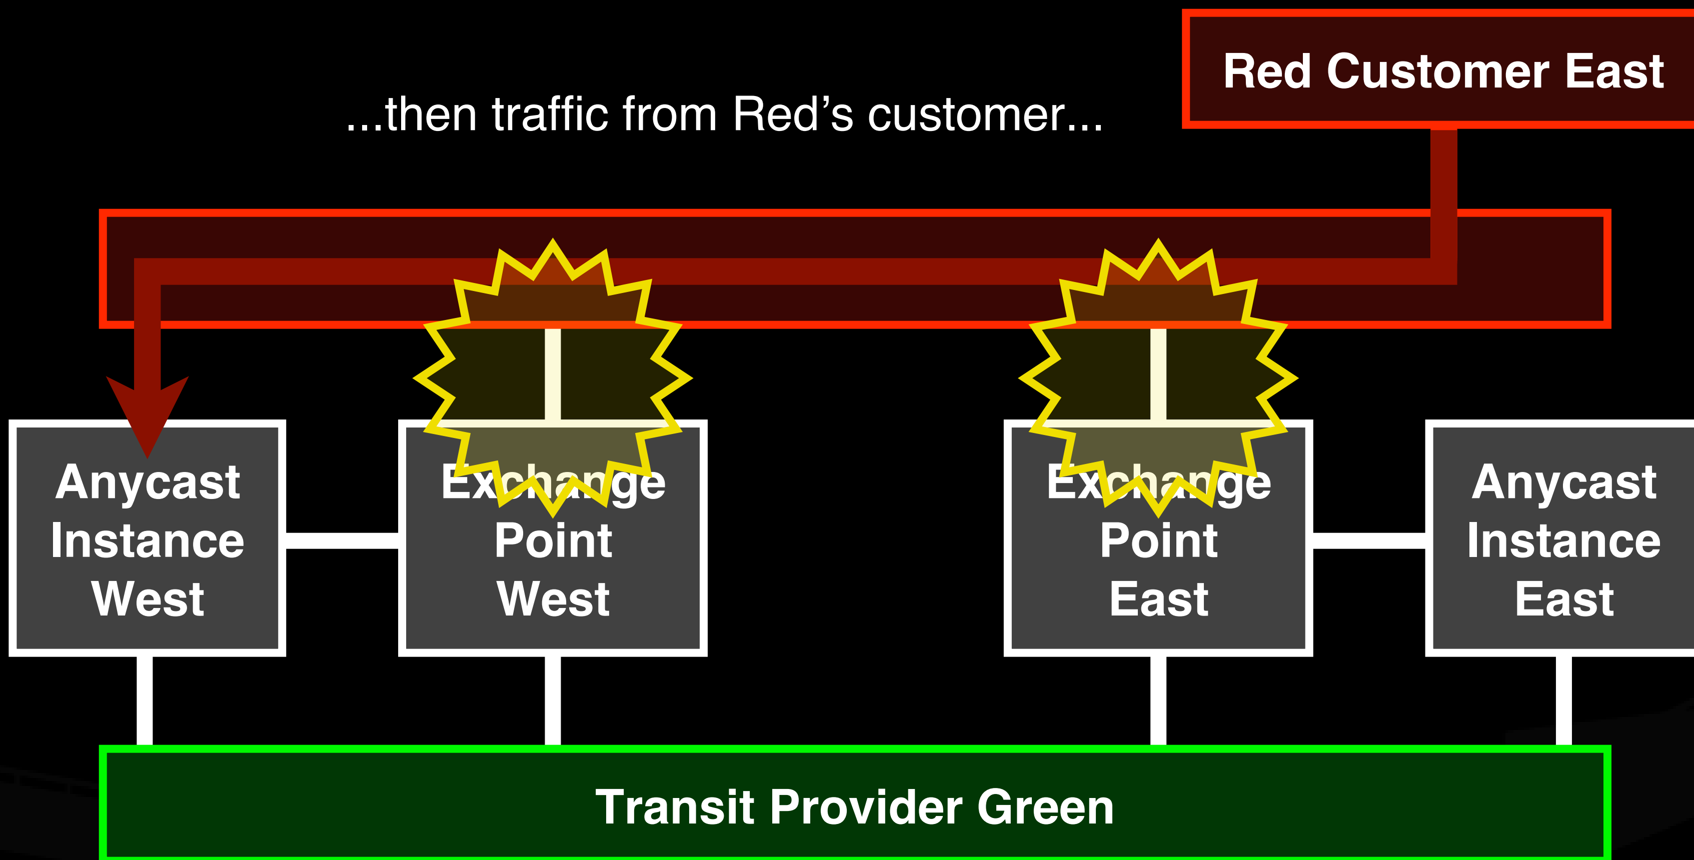
# How the Conflict Plays Out

...then traffic from Red's customer...



...will be misdelivered to the remote anycast instance, because a customer connection...

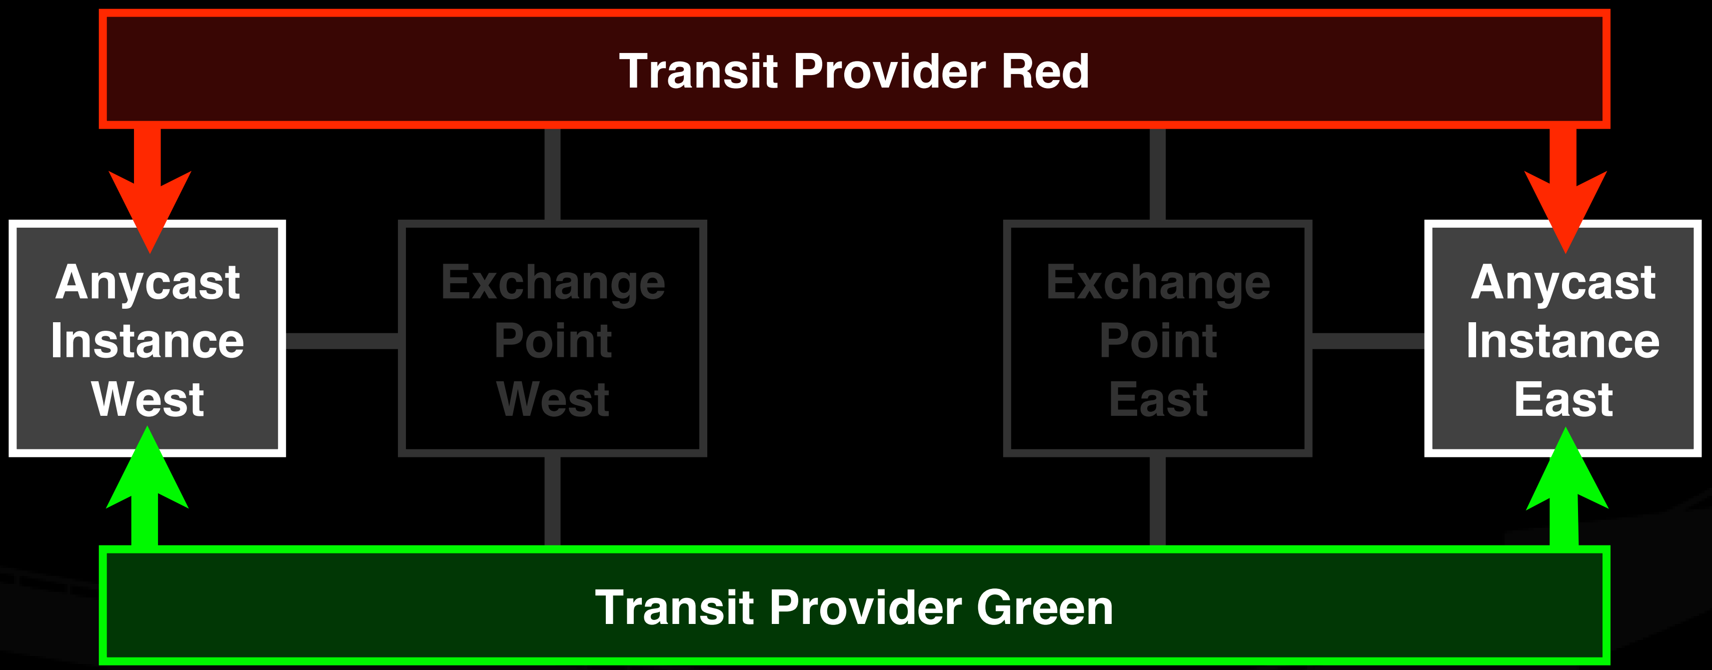
# How the Conflict Plays Out



...will be misdelivered to the remote anycast instance, because a customer connection is preferred for economic reasons over a peering connection.

# Resolve the Conflict

Any two instances of an anycast service IP address must have the same set of large transit providers at all locations.



This caution is not necessary with small transit providers who don't have the capability of backhauling traffic to the wrong region on the basis of policy.

Packet Clearing House

# Putting the Pieces Together

- We need an A Cloud and a B Cloud.
- We need a redundant pair of the same transit providers at most or all instances of each cloud.
- We need a redundant pair of hidden masters for the DNS servers.
- We need a network topology to carry control and synchronization traffic between the nodes.
